Exploring weavable patterns using matrices

David O'Sullivan

2021-10-29

```
library(pracma)
library(tidyr)
library(dplyr)
library(sf)
library(tmap)
library(raster)
library(RColorBrewer)
```

This function makes a random pattern (as a matrix of values) from two provided list of (distinct) integers. Default values will make a 4 x 4 repeating unit.

The repeat_warp and repeat_weft parameters will specifying how many times across and down respectively to repeat the pattern.

```
make_random_pattern <- function(warp = seq(1, 24, 6), weft = seq(27, 50, 6),
                                  repeat_warp = 4, repeat_weft = 4) {
  size <- length(warp) * length(weft)</pre>
  mat <- matrix(sample(0:1, size, replace = TRUE), 4, 4)</pre>
  treadling <- diag(length(weft)) %>%
    # matrix(sample(0:1, size, replace = TRUE),
                          nrow = length(weft), ncol = length(warp)) %>%
    repmat(m = repeat_weft, n = 1)
  threading <- diag(length(warp)) %>%
    # matrix(sample(0:1, size, replace = TRUE),
                         nrow = length(weft), ncol = length(warp)) %>%
    repmat(m = 1, n = repeat_warp)
  ww <- threading %*% mat %*% treadling > 0
  fabric <- matrix(0, nrow = nrow(ww), ncol = ncol(ww))</pre>
  for (i in seq_along(weft)) {
    rows <- seq(i, nrow(ww), length(weft))</pre>
    idxs <- which(ww[rows, ])</pre>
    fabric[rows, ][idxs] <- weft[i]</pre>
  for (i in seq_along(warp)) {
    cols <- seq(i, ncol(ww), length(warp))</pre>
    idxs <- which(!ww[, cols])</pre>
    fabric[, cols][idxs] <- warp[i]</pre>
  return(fabric)
```

This function makes an sf polygon from a list of coordinate supplied as an (x1, y1, x2, y2, ...) list.

```
# convenience function to make a sfc POLYGON from a vector
# of points as c(x0,y0,x1,y1,...xn,yn) - note not closed
# this function will close it
get_polygon <- function(pts) {
   mpts <- matrix(c(pts, pts[1:2]), ncol = 2, byrow = TRUE)
   return(st_polygon(list(mpts)))
}</pre>
```

A function to translate a polygon by the supplied (x, y). The ordering of parameters facilitates use in an lapply.

```
shift_poly <- function(pt, poly) {
  return(poly + pt)
}</pre>
```

Function to make an **sf** dataset from the supplied matrix. **w** specifies the size of the grid elements in the units of the provided CRS.

```
make polygons from matrix <- function(width, mat, crs) {</pre>
  dxdy \leftarrow expand_grid(x = 0:(ncol(mat) - 1),
                      y = 0:(nrow(mat) - 1)) %>%
    mutate(x = width * x, y = width * y) %>%
    # next steps convert to a list of coordinate pairs
    t() %>%
    as.data.frame() %>%
    as.list()
  # base polygon centred on (0, 0)
  p <- get_polygon(width / 2 * c(-1, -1, 1, -1, 1, 1, -1, 1))
  # the ids from the supplied matrix (these should be integers)
  ids <- c(mat)</pre>
  return(
    # apply the dxdy offsets to the base polygon
    lapply(dxdy, shift_poly, poly = p) %>%
      # and convert to an sf dataset
      st_as_sfc() %>%
      st sf() %>%
      st_set_crs(crs) %>%
      # add in the id attribute and dissolve
      mutate(id = ids) %>%
      group_by(id) %>%
      dplyr::summarise()
}
```

In use

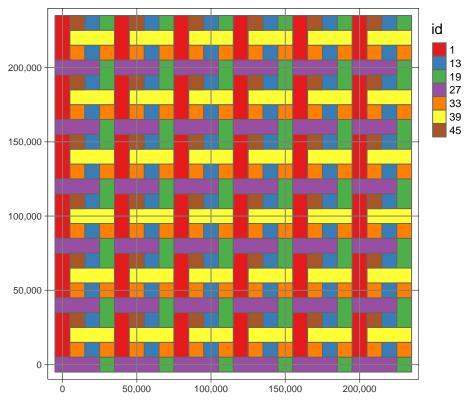

As a vector map

```
tmap_mode("plot")

## tmap mode set to plotting

make_polygons_from_matrix(
   10000, # big enough to see on a web map!
   make_random_pattern(repeat_warp = 6, repeat_weft = 6), 3857) %>%
    tm_shape() +
```

```
tm_polygons(col = "id", style = "cat", palette = "Set1") +
tm_grid() +
tm_layout(legend.outside = TRUE)
```

As a raster stack

It's nice to see a bunch all at once. It's easy enough to use image() to plot the patterns, but it's a pain to arrange them in a grid. Handled as a raster stack tmap does the job nicely!

```
layers <- list()
for (i in 1:70) {
   layers[[i]] <- raster(make_random_pattern(), crs = st_crs(3857)$wkt)
}
r <- stack(layers)
tm_shape(r) +
   tm_raster(palette = "Accent", style = "cat")</pre>
```
